ABSTRACT

A quartz-enhanced photoacoustic spectroscopy (QEPAS) based multi-gas sensor was developed to quantify concentrations of carbon monoxide (CO), hydrogen cyanide (HCN), hydrogen chloride (HCl), and carbon dioxide (CO₂) in ambient air. The sensor assembled in a compact package of dimensions 25cm x 25cm x 10cm was designed to operate at atmospheric pressure. The HCN, CO₂, and HCl measurement channels are based on cw, C-band telecommunication-style packaged, fiber-coupled diode lasers, while the CO channel uses a TO can-packaged Sb diode laser as an excitation source. The sensor incorporates rechargeable batteries and can run on batteries for at least 8 hours. It can also operate autonomously or interact with another device (such as a computer) via a RS232 serial port. Trace gas detection limits of 7.74ppm at 4288.29cm⁻¹ for CO, 450ppb at 6539.11 cm⁻¹ for HCN, 1.48ppm at 5739.26 cm⁻¹ for HCl and 97ppm at 6361.25 cm⁻¹ for CO₂ for a 1sec average time, were demonstrated.

Keywords: quartz-enhanced photoacoustic spectroscopy (QEPAS), portable multi-gas sensor, distributed-feedback diode laser, quartz tuning fork, laser spectroscopy, trace gas detection

1. INTRODUCTION

Carbon Monoxide (CO), hydrogen cyanide (HCN), hydrogen chloride (HCl), and carbon dioxide (CO₂) are post-combustion products in aerospace materials used in spacecraft and the international space station environments. Their absence in a post-combustion environment is a reliable indicator for mission specialists (astronauts) that the air quality is below the spacecraft maximum allowable concentrations for airborne contaminants (SMAC values). Therefore, the development of a compact, multi-gas sensor for early fire detection is of considerable interest [1, 2], specifically since targeting of multiple potential fire gases reduces false positives and negatives.

Figure 1. Photograph of quartz tuning forks.

Quartz-enhanced photoacoustic spectroscopy (QEPAS) is based on the use of a quartz tuning fork (QTF) as a

*Lei.dong@rice.edu; phone 1 713 348-5418; fax 1 713 348-5686

detector for acoustic oscillations induced in an absorbing gas by modulated optical radiation [3, 4]. The QTF, as shown in Fig. 1, is a piezo-electric element which converts its deformation into separation of electrical charges. Due to its geometry and arrangement of the electrodes deposited on the quartz crystal (see the right hand side of Fig. 1), the QTF is selectively sensitive to the sound originating in a small, 100-300 μm wide, space between its prongs. In order to enhance the sound signal, an acoustic micro-resonator was employed in most reported QEPAS based gas sensors [5]. It consists of two short pieces of rigid stainless tubing placed along the excitation laser beam direction and positioned close to, but not touching, the QTF, with 30-50 μm gaps. Such a micro-resonator will increase the QEPAS detection sensitivity up to 30 times higher than a bare QTF. The QEPAS technique allows the analysis of gas samples ~3 mm³ in volume, results in immunity to environmental acoustic noise, and the QEPAS detection module size matches the size of telecommunications diode lasers so that a QEPAS based sensor can be very compact.

In this paper, we design and perform a compact QEPAS four-gas sensor using near infrared laser diodes for early fire detection in detail. The sensor is specifically designed to detect and quantify concentrations of CO, HCN, HCl, and CO₂ in ambient air.

2. Spectral lines selection for CO, HCN, HCl and CO₂

Figure 2 depicts the spectra of CO, HCN, HCl and CO₂ between 1000-9000 cm⁻¹ obtained from the HITRAN08 database. The fundamental and the first two overtones of carbon monoxide are located at 4.7μm, 2.3μm and 1.6μm, respectively. For CO detection, we selected the line at 4288.29 cm⁻¹ (2.3 μm) as the optimum target line.

![Figure 2: Absorption lines of CO, HCN, HCl and CO₂ between 1000-9000 cm⁻¹.](image)

Carbon dioxide has several rotational-vibrational spectra in the near infrared region. For example, its ν₁ fundamental, 2ν₁ and 3ν₁ overtone band are located at 4.25 μm, 2.15 and 1.43 μm, respectively; its 2ν₁+2ν₂+ν₃ combination band is located at 1.573 μm; and its ν₁+2ν₂+ν₃ combination band is located at 2 μm. Due to the ~370 ppm background in ambient air, the CO₂ sensor does not require a high sensitivity. Therefore a line at 6361.25 cm⁻¹ (1.57 μm) is used.
The infrared spectra of hydrogen cyanide are located at 6.9 μm, 3 μm and 1.5 μm. The 3 μm band is the ν3 fundamental band. We selected 6539.11 cm⁻¹ (1.529 μm) as the HCN target line due to its strong line strength and the available diode laser output power at 1.5 μm.

HCl detection is possible in the ro-vibrational fundamental band (4 μm), as well as in the first (1.8 μm) and the second (1.2 μm) overtone band. We selected an absorption line located at 5739.26 cm⁻¹ (1.742 μm).

3. Design of multi-gas sensor

3.1 CO₂, HCl and HCN sensing channels

The wavelength of the target lines of CO₂, HCl and HCN are in the telecommunication spectral range as mentioned above. In this spectral range the diode laser sources are available in a standard 14-pin butterfly package, including an integrated isolator, TEC control, and a single mode fiber pigtail. These features make these diode laser sources extremely convenient and easy to use in our multi-gas sensor design.

![Diagram of a single diode laser sensing channel](image)

**Figure 3.** Schematic of a single diode laser sensing channel. DL—diode laser; BS—beam splitter; FC1, FC2—fiber collimator; RC—reference cell; PD—photo detector; ADM—acoustic detection module

The schematic of a single diode laser sensing channel is shown in Fig. 3. The diode laser output is divided in a 1:99 ratio by means of a fiber coupler. 1% of the diode laser light is fiber coupled to a commercial reference module containing a sealed cell filled with a target gas mixture, a fiber collimator, and a photodiode. The remaining laser power is directed to a spectrophone consisting of the QTF and two metal tubes forming the acoustic micro-resonator. The length of each tube is 4.4 mm and the inner diameter is 0.51 mm. The tubes are positioned 0.6 mm below the QTF tips. The spectrophone was placed into an enclosure equipped with a collimator and BK7 window with antireflection coating, as shown in Fig.3 (top). This assembly represents an acoustic detection module (ADM).
3.2 CO sensing channel

The optimum CO absorption line is located at 2.3 μm, and at this wavelength a diode laser is only available commercially as a TO5.6 package without a fiber pigtail and TEC control. Hence it was necessary to design a sensing channel that includes discrete components such as a TEC and lens for collimating the diode laser beam to the QTF. In order to make full use of the diode laser power, the TO5.6 can window was removed in order for the focusing lens to be close to the laser chip. The detailed laser assembly is shown in the left hand side of Fig. 4. The complete CO sensing channel is shown on the right hand side of Fig. 4, which includes a laser assembly, spectrophone, reference cell and photodetector.

The laser is mounted into a small copper housing. Two small TEC were attached to the wall of the copper housing to control the laser temperature. The coupling lens whose working distance is 1.76 mm is glued in front of laser housing to focus the output beam between the two prongs of the QTF. The alignment procedure of the diode laser beam is based on precision CNC machining and a passive alignment method. This method reduces significantly labor costs. Furthermore, such a micromechanical approach is suitable for manufacturing large numbers of identical, interchangeable spectrophones. Upon exiting the QTF the laser beam is directed to a reference cell by a 90° reflector and is monitored by a photo detector. The reference signal is used to lock the laser frequency to the CO target line.

3.3 Control electronics unit (CEU) and assembly of a diode laser based QEPAS multi-gas sensor

All the four sensing channels (CO, HCN, HCl and CO₂) are mounted inside the control electronics unit (CEU) with dimensions of 10 x 25 x 25 cm, as shown in Fig. 5. The CEU performs the frequency locking functions of the laser wavelengths to the four target absorption lines, as well as measuring the QTF parameters, and modulating the diode lasers at half the resonant frequency of the corresponding QTFs. To determine the QTF parameters, an electrical, sine wave excitation voltage is applied, and the excitation frequency is scanned to determine the QTF natural frequency by measuring the QTF current. The Q-factor was derived from the QTF ringdown time following a sudden interruption of the excitation voltage. Four sets of parameters have been pre-programmed in the CEU, each set includes the selected diode laser, a reference cell, a spectrophone, laser current and temperature, modulation depth, and control parameters. The CEU can be programmed to loop though the desired sets of parameters in an autonomous mode.

Also, the CEU can communicate with an external computer through RS 232, receiving commands and exchanging data. It also includes rechargeable batteries so that the sensor is able to operate on battery power for >8 hours. All 4 ADMs are open cell design. In order to ensure efficient gas exchange between ambient air and the internal sensor case volume, the CEU is equipped with a fan. Therefore, the sensor does not require a vacuum pump, which reduces the overall sensor weight.

4.2 Linearity of the sensor response

The linearity of the multi-gas sensor response was evaluated. The results are shown in Fig. 6. A linear response evaluation of the HCl sensor was not performed since only a 10 ppm HCl cylinder was available. The accuracies and linear ranges of the CO, HCN and CO₂ channels were good as shown in Fig. 6.

Figure 6. Linear response of CO, HCN and CO₂ sensing channels.

4.3 Gas humidity impact

Figure 7. Impact of humidity on CO₂ signal.
In photo acoustic spectroscopy, the vibrational-translational (V-T) relaxation rate of gas plays an important role. In case of a slow V-T relaxation rate with respect to the modulation frequency, the translational gas temperature cannot follow fast changes of the laser induced molecular excitation rate. Thus the generated photoacoustic wave is weaker than it would be in case of instantaneous V-T energy equilibration. However, the presence of H2O can increase the V-T relaxation rate of the target gas. Figure 7 shows the impact of water vapor on CO2 signal. When the relative humidity is >0.2%, the V-T relaxation rate is saturated, and the measured QEPAS signal is no longer impacted by humidity. Similar studies were performed for CO, HCl and HCN. The impact curves are used to calibrate the QEPAS output signals.

4.4 Test data of QEPAS multi-gas sensor

![Graphs showing CO2 and HCl concentration over time](image)

Figure 8. QEPAS signal of compact multi-gas sensor recorded for varied gas concentrations obtained using a commercial gas mixer.

Each of the four sensor channels shows 4-second averaged-response data as discrete dots and a 40-second running average as a solid line. The 4-second averaged-respond data can reflect the instantaneous change of the gas concentration, while the 40-second average measures the precise gas concentration. Figure 8 shows the recorded signals while the gas concentration was varied by a gas mixer.

5. Summary

In this paper, we designed, assembled, and assessed a compact portable multi-gas sensor, which can quantify CO, CO2, HCl and HCN simultaneously. We demonstrated detection sensitivity limits (1 second averaging time) of 7.7 ppm for CO, 450 ppb for HCN, 1.5 ppm for HCl and 100 ppm for CO2 respectively. Our measurements show that the compact, multi-gas sensor based on 3 near-infrared DFB communications and one Sb diode lasers is applicable for early fire detection.

ABSTRACT

The air quality of any manned spacecraft needs to be continuously monitored in order to safeguard the health of the crew. Any fire event, accidental release of harmful gaseous contaminants or a malfunction in the air revitalization system has to be detected as fast as possible to provide enough time for the crew to react. In this paper, a fast sensor system based on laser spectroscopy is presented, which is able to detect three important gases: carbon monoxide for fire detection, hydrogen chloride for fire characterization and oxygen to monitor the air revitalization system. To provide a long maintenance-free operation time without the need for any consumables except power, a calibration-free measurement method was developed, which is only based on molecule specific constants which are available from the molecular data base HITRAN. The presented sensor offers the possibility for reliable and crosssensitivity-free air quality monitoring over a large pressure and temperature range.

Keywords: laser spectroscopy, gas analysis, combustion monitoring

1. INTRODUCTION

Any event of fire aboard a spacecraft has to be detected and identified as fast as possible to prevent damages of instruments that are essential for the life of the crew and to avoid contamination of the air with harmful gases. Different gases are suited as markers for different kind of combustion events. Model pyrolysis of different materials have shown that e.g. during the combustion of PVC (cable fire) significant concentrations of hydrogen chloride have been produced, whereas during the combustion of a PC circuit board no hydrogen chloride has been detected. Monitoring of a limited number of different gaseous compounds can help to identify what kind of material is burning and how the fire has to be extinguished in order to minimize the risk of contamination with harmful gas compounds.

For this application there is a need for a fast, reliable, compact and low-power gas sensor, which is able to detect harmful trace gases in very small concentrations as well as oxygen to monitor the air revitalization system. According to possible scenarios in manned spacecrafts, the sensor has to be operated in a wide pressure range between 8 and 15 psi, needs a fast response time of less than 2 s and a maintenance-free operation time of more than 10 years.

In this paper, a sensor system based on tunable diode laser spectroscopy is presented, which is able to detect three important gases: two harmful trace gases, carbon monoxide and hydrogen chloride, as well as oxygen. Its design is optimized to offer maximum sensitivity at minimum sensor dimensions. The use of vertical-cavity surface-emitting lasers with threshold currents below 5 mA reduces the power consumption to a minimum. A calibration-free measurement method is presented, which is only based on molecule specific constants which are available from the molecular data base HITRAN. With this technique, there is no need for a recalibration of the sensor which is the basis for long maintenance-free operation times.
